**Simple Summary:** Humans have interacted with reptile and amphibian species for millennia. The current study was designed to collect knowledge about the use of amphibian and reptile species by the native peoples residing along the Jhelum and Chenab rivers in Punjab, Pakistan. To the best of our knowledge, this is the first quantitative assessment of the cultural uses of amphibian and reptile species in the study area. However, hunting, trade, and cultural use are the greatest threats to the diversity of the amphibians and reptiles in the studied area. These threats can potentially lead to their extinction. It is important to protect the highly endangered and vulnerable species employed in therapeutic medications, more specifically in terms of their conservation.

**Abstract:** Amphibians and reptiles have interacted with humans for millennia. However, humans interact with amphibian and reptile species in different manners, which depend on their culture and traditions. This study was designed to better understand the interactions between amphibian and reptile species and their usage among the native peoples in the vicinity of the Jhelum and Chenab rivers, Pakistan. Information was collected through semi-structured interviews and questionnaires, and was analyzed by using different indices, including the frequency of citation, corrected fidelity level, fidelity level, relative importance level, and informant major ailment. Two amphibians and twenty-six reptile species were used in therapeutic medicine in the study area. Based on the cultural analysis, we found that *Naja naja* (black cobra) was highly cited across all cultural groups. A 100% Fidelity Level was calculated for the following species: *Naja naja* (eye infection), *Varanus bengalensis* (joint pain), *Eurylepis taeniolatus* (cataract), and *Acanthodactylus cantoris* (cancer). We found five endangered species in the study area, i.e., *Aspideretes gangeticus*, *A. hurum*, *Chitra indica*, *Varanus flavescens*, and *Geoclemys hamiltonii*, that were used to cure joint pain, muscle stretching and pain, backbone pain, paralysis, and psoriasis, respectively. Likewise, *Lissemys punctata andersoni*, a vulnerable species as labelled by the International Union for Conservation of Nature, was extensively used for the treatment of joint pain, body pain, paralysis, and arthritis in the study area. In terms of conservation, it is critical to protect the highly vulnerable and endangered species that are being used in therapeutic medicines. Our findings may be helpful for the conservation of amphibian and reptile species by helping to make an effective plan to prevent their extinction. The main threats to the diversity of amphibian and reptile species in the area are hunting, trading, and cultural use. These threats could potentially lead to the extinction of these species. Therefore, with the involvement of concerned authorities, e.g., local stakeholders, the Ministry of Climate Change, provincial wildlife departments, academia, and conservation managers, immediate conservation measures should be taken for the protection and sustainable utilization of medicinal species.

## 1. Introduction

Amphibians and reptiles are used for many purposes, including for food [1], art [2], pharmacology [3–5], calligraphy [6], culture [7], poetry [8], entertainment [9,10], religion [11], and clinical studies [12]. It has been observed that the interaction with amphibians and reptiles is valuable for maintaining good health [13,14]. The body products of amphibians and reptiles are utilized in Ethnomed. and nanomedicine [15–17]. Many species of amphibians and reptiles have significant value to humans [18,19]. Amphibians and reptiles are under direct threat due to the dangers of human activities such as road accidents [20], medicinal uses [17], illegal hunting, and trade [21], along with indirect threats such as the deforestation and modification of land [10,22–28]. Amphibians and reptiles are known as “diversified fauna” [29–31]. So far, an estimated 7850 amphibians and 10,450 reptiles have been documented around the world [32]. Khan [33,34] reported 24 amphibian species and 195 reptile species in Pakistan. Many different species of amphibians and reptiles are utilized in traditional and folklore medicine to cure ailments in other countries [24,31,35]. Humans exploit many of these species by using derived products such as meat, eggs, oil, blood, skin, shells, bones, and other body parts as natural products for tools, medications, decorations, food, and for magical and religious purposes [36,37].

In recent years, there has been increasing recognition for the importance of ethnobiological studies for biodiversity conservation. Ethnobiological research is essential for comprehending the sustainability of biocultural systems [38,39]. Moreover, ethnobiology offers critical insights into the customs of local peoples, enabling conservation efforts to collaborate with resource guardians to successfully promote the overall integrity of biocultural systems [40]. Cultural uses of animals (e.g., medicine, food, hunting, trade, entertainment, and religious practice) may promote beliefs and behaviors that aid in the conservation [41,42]. However, if these practices are being carried out in an unsustainable manner, or are influenced by economic, commercialization, and political factors, they may have a negative impact on or even endanger these animals [41]. It is important to consider other aspects, such as the changes in environment and climate, when analyzing how people use specific animal species for medicinal and cultural purposes [43,44]. The current challenge of biodiversity loss requires new strategies to be developed on a global scale [45].

Humans have interacted with animals for millennia, where the interaction reflects the impact from both culture and environmental conditions [42]. Depending on the desired usage and accompanying cultural characteristics, a single species can be employed in a variety of ways and for a variety of purposes by various communities [46–48]. Animals generally interact with humans due to their utility or the hazards they represent [47]. Furthermore, numerous myths, proverbs, and legends have arisen from these interactions and have been orally transmitted from generation to generation, affecting how the indigenous peoples interact with the animals [25,48]. Depending on the culture and region, different animals are exploited to different degrees. Direct exploitation is a major threat to biodiversity [49]. However, this includes timber exploitation and the acquisition of terrestrial as well as aquatic species for human use. Specifically, the use of reptiles as pets has been increasing around the world, generating high-value international trade with important implications for animal conservation. This trade of pets at high prices poses a hazard to numerous species that are often vulnerable [50,51]. Such species, including those recently described by the literature, frequently are of significant interest to collectors [52,53]. The presence of a species on Appendix I or II of CITES that would forbid or control its international trade is frequently compromised by a lack of data, economic interests, and the reality that conferences of the groups only occur every 3 years [54,55]. To ensure the survival of animal populations, conservationists must comprehend not only the ecological, but also

the economic and cultural linkages that interconnect social and ecological systems into a single regional system, as well as the feedback that regulates these relationships.

Punjab is the second largest province in Pakistan after Baluchistan. The inhabitants of the Punjab province have diverse traditional knowledge and practices because of the great linguistic and cultural diversity present in the region [56]. The Jhelum people of Punjab widely use herptiles for ethnomedicinal purposes, e.g., *Aspideretes gangeticus*, *Daboia russelii*, *Ptyas mucosa*, etc. [7]. The diversity of herptiles has been documented by many authors [5,28,33,57–59], while the conservation aspects or direct uses have been observed only by a few researchers [3,7] in Pakistan. To the best of our knowledge, this is the first quantitative assessment of the cultural and medicinal uses of amphibian and reptile species in the study area. This study was designed to gain knowledge about the usage of amphibian and reptile species by the native peoples residing along the Jhelum and Chenab rivers in Punjab, Pakistan. We endeavored to give answers to the following questions: 1. How many amphibian and reptile species are employed in therapeutic medication in the healthcare system of Punjab, Pakistan? 2. Which species are the most frequently used? 3. What are the reasons for using amphibians and reptiles for medicinal purposes? 4. What are the key socioeconomic factors influencing the use of amphibians and reptiles for medicinal purposes (income, age, education level, and religion)? 5. What are the conservation consequences of using amphibian and reptile species for medicinal purposes?

## 2. Materials and Methods

### 2.1. Study Area and Native People

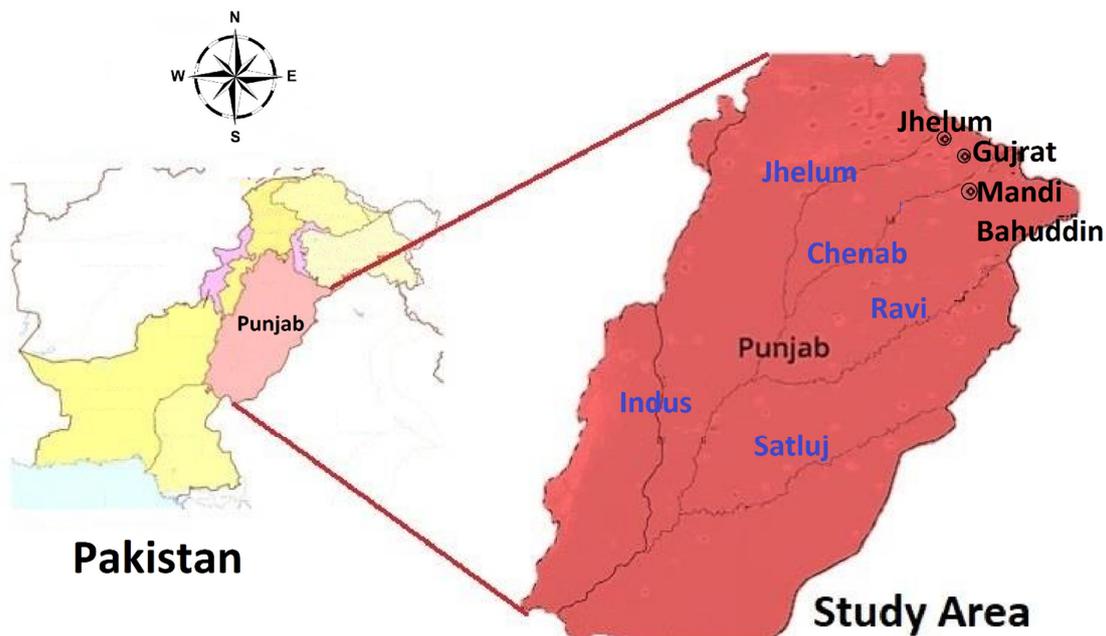

The present study was conducted between 2018 and 2020 in the Chenab and Jhelum riverine areas, i.e., Mandi Bahauddin (204 m elevation), Jhelum (234 m elevation), Gujranwala (231 m elevation), and Gujrat (233 m elevation) (Figure 1). The Jhelum people are agro-pastoralists, where they live in villages, grow crops, and use pastures for grazing livestock. Jhelum has no plains [60,61]. The languages of the local people are Punjabi and Pothohari [62]. The Chenab River originates in the state of Himachal Pradesh, India and continues into Pakistan [63]. While Punjabi is the common language, some people can speak Saraiki, Hindku, Pahari, and Urdu, while some people can also speak English to some extent [64–66]. The temperature starts near 0 °C in December and ends at 50 °C in June [64–66]. This agroforest land has a rich diversity of flora and fauna [23,33,67–71]. Most of the population is peri-urban, and it includes the Jutt, Sheikh, Arain, Gujjar, Malik, Mughal, Rana, and Butt casts.

### 2.2. Data Collection and Analysis

Before the start of the survey work, proper permission was obtained from the Department of Zoology at the University of Lahore, District Sargodha, Punjab. To acquire information on the therapeutic uses of amphibian and reptile species, semi-structured interviews and group discussions were conducted with 100 participants, after obtaining oral prior informed consent. Interviews were conducted during the daytime, and specimens (e.g., pictures, carcasses, etc.) were also collected during different visits. Informants were randomly gathered [41,72]. Some herpetofauna images were included in the questionnaires, and the semi-structured interviews contained questions about the local names of species and their ability to harm, as well as their applications in medicine, food, magic, narratives, superstitions, hunting, religion, and entertainment (Supplementary Material Table S1). Respondents' age, sex, educational status, and linguistics were collected as demographic data. The questionnaires were first written in English (Table S1), and then translated into Punjabi, Saraiki, and Urdu.

Amphibian and reptile species in the study area were directly identified by the respondents and confirmed. This was accomplished through photos included in the questionnaire and sent by e-mail or Facebook messaging. Amphibians and reptiles were confirmed by using *Amphibian and Reptiles of Pakistan* [33] for the correct identification and classification of the amphibians and reptiles in the study area [73]. The conservation status of each

species was checked by consulting the Red List of Threatened Species of the International Union for Conservation of Nature and Natural Resources.

**Figure 1.** Map of the study area.

Informants were of a minimum age of 18 years and a maximum age of 91 years old (Supplementary Material Table S2). In the study's survey, information was collected from male and female participants. Informants were told about the aims of the research after their permission to contribute to the data was obtained and they were guaranteed that their identities would be kept secret. The information about different usages of the animals' body parts and their modes of application were shown in chord diagrams using the 'circlize' package in R software 3.6.1 [74]. Different indices were used to analyze the ethno-herpetological data, including the frequency of citation, corrected fidelity level, fidelity level, relative importance level, and informants of major ailment.

### 2.3. Frequency of Citation (FC)

The FC indicates the number of informants who reported the use of the animal species in medicine [75].

### 2.4. Fidelity Level (FL)

The FL was measured to determine the important species that were used by local peoples to treat specific ailments [75]. Its calculation is accomplished by using the following formula [76].

$$FL (\%) = (IMA/FC) \times 100 \quad (1)$$

IMA shows the number of informants who informed about the use of amphibian and reptile species for specific disease treatment, while FC is the total informers of a particular species.

### 2.5. Relative Importance Level (RIL)

The RIL was used to represent the level of popularity of different species in the study region. RIL is calculated using Equation (2), in which the number of respondents who claimed to use a single species (IMA) is divided by the sum of all respondents who claimed to use all species in the study area. The correction scale (CS) is used to distinguish between the popular and unpopular species. The RIL value ranges from 0 to 1.0. When animal species are used to obtain maximum ailment purposes, the RIL will increase from

zero to the maximum value of '1', while if the popularity of species for ailment purposes decreases, then the value will move from '1' to '0', showing divergence away from usage importance. [77,78].

$$RIL = FC/FCt \quad (0 < RIL < 1) \tag{2}$$

2.6. Corrected Fidelity Level (CFL)

The CFL was utilized as a factor of correction to find out the exact rank of animal species with dissimilar FL and RIL values. The CFL index was obtained by utilizing the following formula [77,78].

$$CFL = FL \times RIL \tag{3}$$

2.7. Ethics Approval

The proposed research on animals (especially amphibians and reptiles) was duly approved by the institutional committee of the Department of Zoology at the University of Lahore, Sargodha, Punjab, with a focus on the intellectual property rights of informants before the filed survey. In addition, the ethical guidelines and rules of the International Society of Ethnobiology (ISE) (<http://www.ethnobiology.net/> accessed on 12 July 2018) were strictly followed.

3. Results

A total of two amphibians (7%) and twenty-six reptiles (93%) were used for therapeutic medicines in the study area. Data were documented from 100 respondents, whose ages ranged from 18 to 91 years (Figure 2). About 75% of the respondents were literate, with educations including Masters of Philosophy (2%), Masters degree (3%), Bachelor's degree (2%), intermediate (10%), matriculated students (32%), middle school (20%), and primary school (6%). The use of amphibian and reptile species was more frequent among the illiterate people (25%). Most of the participants (75%) were from rural areas with an agriculture background (Figure 2). Most of the people in the study area were poor, and because traditional therapy is cheaper, they prefer folk medicine.

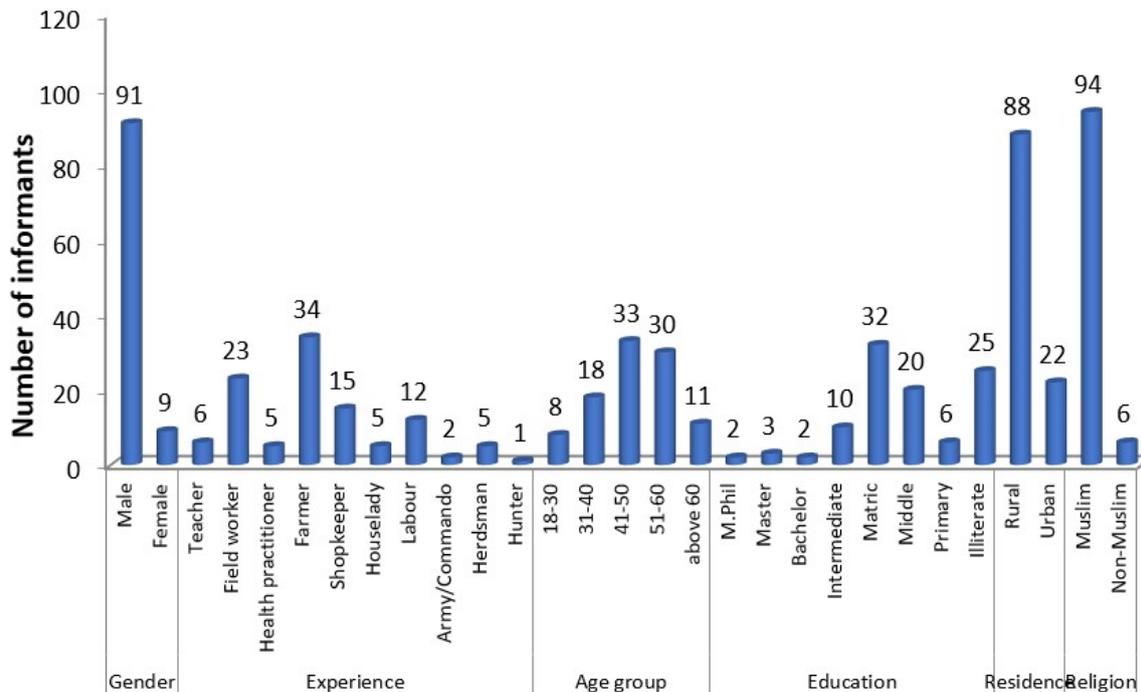

Figure 2. Numbers of study participants in the adjacent areas of the Chenab and Jhelum rivers, Punjab province, Pakistan. Respondents of different age groups, occupations, experiences, religions, residences, and educations were interviewed.

### 3.1. Principal Component Analysis

A principal component analysis was conducted with MD (medicinal), NR (narratives), SS (superstitions), TL (tool), CC (commercial use), ET (entertainment), FD (food), HF (harmful), MG (magic), EX (export), OR (ornamental), and REL (religious) values (Table 1). This analysis was used to highlight a significant difference in the use of amphibian and reptile species for cultural, food, and medicinal purposes, and was separated along the axis-1 ( $p < 0.05$ ) as shown in Figures 3 and 4. The significance of the PCA scores was confirmed by a one-way ANOVA, which calculated the analytic differences between the cultural and medicinal use of amphibian and reptile species. PC1 and PC2 elucidated 92.5% of the variance. The loadings of variables in PC1 showed that only *Naja naja* (black cobra) was positively correlated with cultural values while other species had positive correlations with medicinal use value (Figure 4).

### 3.2. Quantitative Assessment

#### 3.2.1. Fidelity Level (FL)

During the study, the Fidelity Level of amphibian and reptile species varied from 5.88% to 100% (Table 2). A 100% FL was noted for four species used to cure specific ailments, i.e., *Naja naja* for eye diseases and as an energy source to remove body weakness, *Varanus bengalensis* for the treatment of joint pain, *Eurylepis taeniolatus* for cataracts, and *Acanthodactylus cantoris* for cancer.

During the statistical analysis, only 6 species had RIL values of more than 0.70 (Figure 5). The highest value of RIL (1.00) was documented for *Bufo stomaticus* and *Hemidactylus flaviviridis* (Figure 5), followed by *Oligodon taeniolatus* (RIL = 0.83), *Lycodon aulicus* (RIL = 0.73), and *Naja oxiana* (RIL = 0.73) (Table 2). Only two species (*Bufo stomaticus* and *Hemidactylus flaviviridis*) were found to be more popular by the respondents, while other species were unpopular in the study area (Figure 5).

#### 3.2.2. Corrected Fidelity Level (CFL)

The highest CFL (36.5) was observed for *Psammophis leithii* for ailments involving snake, scorpion, wasp bite/sting, and eye infections, followed by *Uromastyx hardwickii* for treatment of joint pain (34.15). *Naja naja* and *Varanus flavescens* were cited for therapy of cancer (20.0) and paralysis (20.0), and *Varanus bengalensis* for joint pain (19.51) (Table 2).

The species' relative importance level (RIL) was determined and classified as popular or unpopular. Numbers represent the species names as they appear in Table 2.

#### 4. Discussion

##### 4.1. Socio-Demographic Data on Participants

Compared with the literate informers, whose exposure to modernization was higher, illiterate people in the research area were found to be less aware of the conservation aspects of reptile and amphibian species. Similar findings were found in Ethiopia [88,89] and Thailand [90]. Many inhabitants of the study area were heavily dependent on reptilian and amphibian species for a variety of purposes, including for supplementing their income. Selected informants belonged to different occupations, such as teachers, field workers, hunters, traditional healers, farmers, shopkeepers, house ladies, government employees, and laborers (Figure 2). We noted that rural informants had less knowledge about the conservation and sustainable use of species as compared with urban participants. Gathering socio-demographic data on participants (sex, age, educational level, occupation, and ethnicity) was thus particularly beneficial in social research, as this element plays a significant role in analyzing and interpreting the responses that were received [91].

##### 4.2. Local Nomenclature

The local names of amphibians and reptiles were generally based on the fauna's sound, environment, habitat, myth, morphological characteristics, and social links with *Homo sapiens*. As documented in Table 1, sap was utilized as a suffix synonym of eleven species of amphibians and reptiles (39.3%), such as *Bungarus caeruleus* (Sangchor sap), *Daboia russelii* (Kodian wala sap), *Lycodon aulicus* (Bhairia sap), *Naja naja* (Sheesh naag sap), *N. oxiana* (Phaniar sap), *Oligodon taeniolatus* (gol dhari sap), *Psammophis schokari* (Saharai sap), *P. leithii* (Patta teer maar sap), *P. condanaru* (Siglee sap), *Ptyas mucosa*

(Choh-mar sap), and *Ramphotyphlops braminus* (Dahga sap). Similarly, two species of lizard (7.14%) had the suffix “goh”, such as *Varanus bengalensis* and *V. flavescens*. Four species of lizard (14.3%) had the suffix “kirli”, i.e., *Laudakia agroransis* (Jungli Kirli), *Traplus agilis kistanensis* (Korh kirli), *Hemidactylus flaviviridis* (Gharailo kirli), and *H. flaviviridis* (Gharailo kirli). Local nomenclature of amphibians and reptiles is also based on their morphology; for example, *Lissemys punctata andersoni* has a green color known as “hara kachopra”, while *Acanthodactylus cantoris* has a blue tail known as “naili-push kirli”. Local names of documented amphibian and reptile species could also be linked with the habitats; for example, *Hemidactylus flaviviridis* being named “ghariallo kirli” and *Bufo stomaticus* being named “ghariallo daddo”, as both species live in the vicinity of houses (ghar). Sahrai sap was used as the name of *Psammophis schokari* because it lives in the desert area (sahara). The vernacular of one snake species was based on their morphology: *Ramphotyphlops braminus*, which has a thread-like structure known as dahga sap.

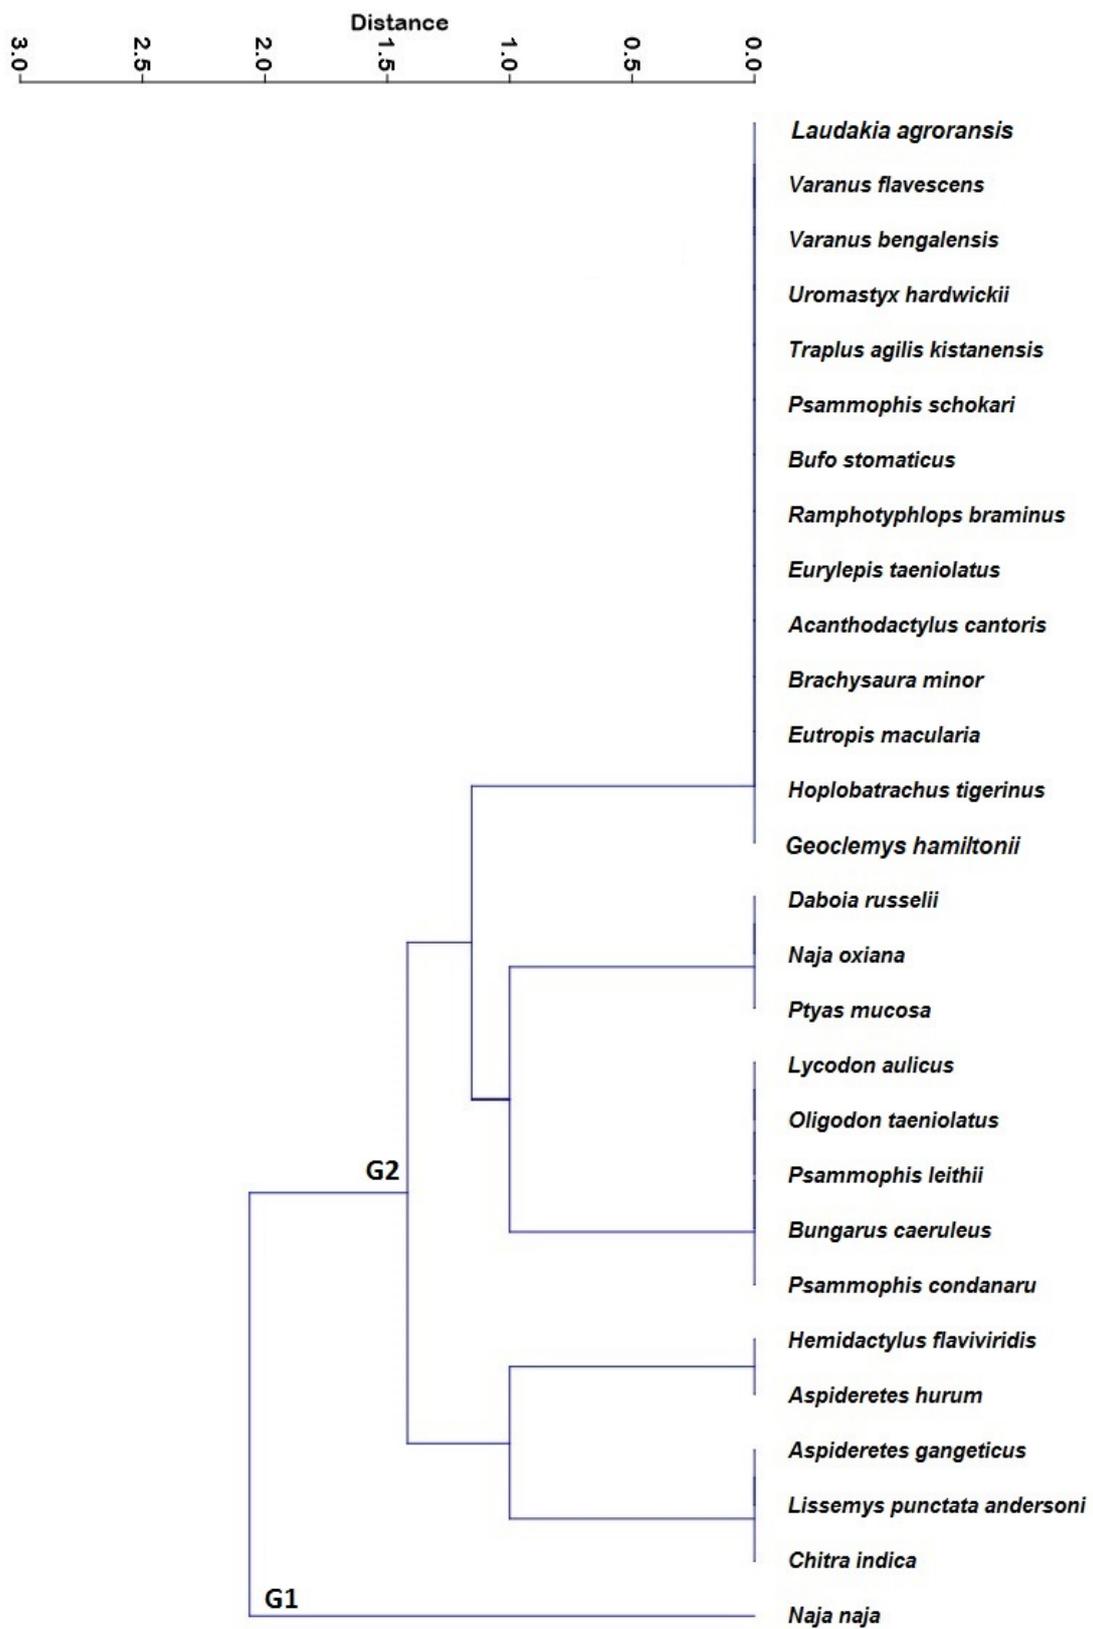

#### 4.3. Cultural Uses of Amphibian and Reptile Species

As shown in Figures 3 and 4, there were important dissimilarities in the use of amphibians and reptiles for cultural, food, and medicinal purposes, separated along the axis-1 ( $p < 0.05$ ). We found that amphibian and reptile species were more commonly used for hunting, superstitious, and medicinal purposes (Figure 4). Reptiles have historically been a significant source of protein for humans across the world [43], and turtles are the most frequently exploited reptiles for human consumption, but snakes, lizards, and crocodiles can also serve as major food sources [92]. According to Alves and Souto [39], freshwater turtles have been reported as an important source of food for Amazonians during the dry season. In our study, non-Muslims ate five species of reptiles, such as *Aspideretes gangeticus*, *Naja naja*, *Lissemys punctata andersoni*, *Chitra indica*, and *Aspideretes hurum* (Table 1).

Amphibians, on the other hand, are generally eaten in lesser quantities than reptiles. Frogs have been consumed locally in many countries as a high-protein source, including in Pakistan [72,93–95]. Amphibians have most likely always been eaten and utilized for cultural purposes in Gabon [96] and Cameroon [97]. Different active agents utilized as potential drugs have been isolated from amphibians [94,98], showing the medicinal importance of amphibians. According to Zhan et al. [94], 11 indole alkaloids and 118 bufadienolide monomers have been isolated from the *Bufo* spp., which exhibit a variety of in vitro and in vivo pharmacological activities, such as detoxification, anti-tumor, immunomodulation, and anti-inflammation.

Based on cultural applications, a cluster analysis revealed two groups of distinct species (Figure 6). The first cluster (G1) showed the highest cited species, including *Naja naja* (black cobra), which was highly cited across all cultural groups (Figure 6). The second cluster (G2) was made up of species with lower citations (Figure 6). Previous research has shown similar groupings. For example, Altaf [99] recorded two groups of wild animals from Punjab, Pakistan, used for cultural purposes by local residents, and eight primary clusters were documented by Rivera et al. [100] in the Castilla-La Mancha (Spain) mountains.

All documented amphibians and reptiles were exported from the Jhelum and Chenab rivers for food, medicine, and ornamental uses. Skins of snakes, such as *Oligodon taeniolatus*, *Naja naja*, *Lycodon aulicus*, *Psammophis leithii*, *Bungarus caeruleus*, *Psammophis condanaru*, *Daboia russelii*, *Naja oxiana*, and *Ptyas mucosa*, were used for decoration (Table 1). Ecologists noted that reptiles are intensively hunted in Pakistan for food, medicine, etc. [10,101]. According to the local informants, all species of amphibians and reptiles were regarded as poisonous and harmful.

**Figure 6.** Cluster analysis showing the similarities between species with different variables (MD, NR, SS, CC, TL, ET, FD, HF, MG, EX, OR, REL) within the study area (G1, i.e., Group One and G2, i.e., Group Two).

#### 4.4. Myths about Amphibians and Reptiles

- Some common myths about amphibian and reptile species were also documented during the field survey (Table 1), as mentioned below. Similar myths were also noted by Altaf et al. [7].
- If someone kills a yellow-bellied common house gecko, God will give a reward to this person.
- If someone kills a Bengal monitor lizard or a yellow monitor lizard, the killer may die.
- All species have poison in their bodies, but they cannot bite because God has prohibited these species.
- All snakes are poisonous.
- All species of lizards have poison in their tails.
- If one of the partners in a pair of female or male snakes is killed by a human, the other will undoubtedly take revenge on the murderer.
- *Naja naja* and *Naja oxiana* change into human beings after the age of 100 years.
- Most people believe that the “Mankana”, a bone in a snake’s head, can absorb venom from any snake that bites a human.

#### 4.5. Medicinal Uses of Amphibians and Reptiles

As documented in Table 2, 28 amphibian and reptile species were utilized to cure different ailments, i.e., wounds, anti-venom, asthma, backbone pain, cancer, cataract, body weakness, eye diseases, hepatitis C, allergy, joint pains, muscle stretching and pain, muscular weakness, paralysis, permanent flu, psoriasis, rheumatism, snake bite, scorpion bite, wasp bite, tuberculosis, tumor, underarm diseases, and vertebrae pain (Figure 7).

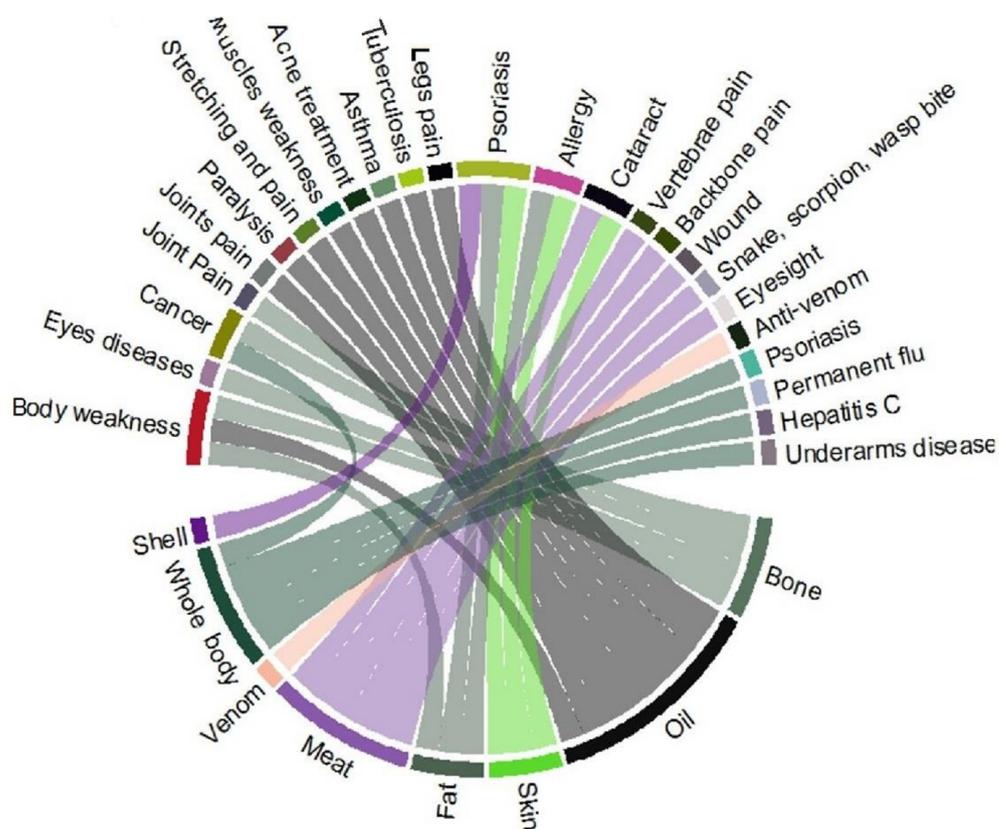

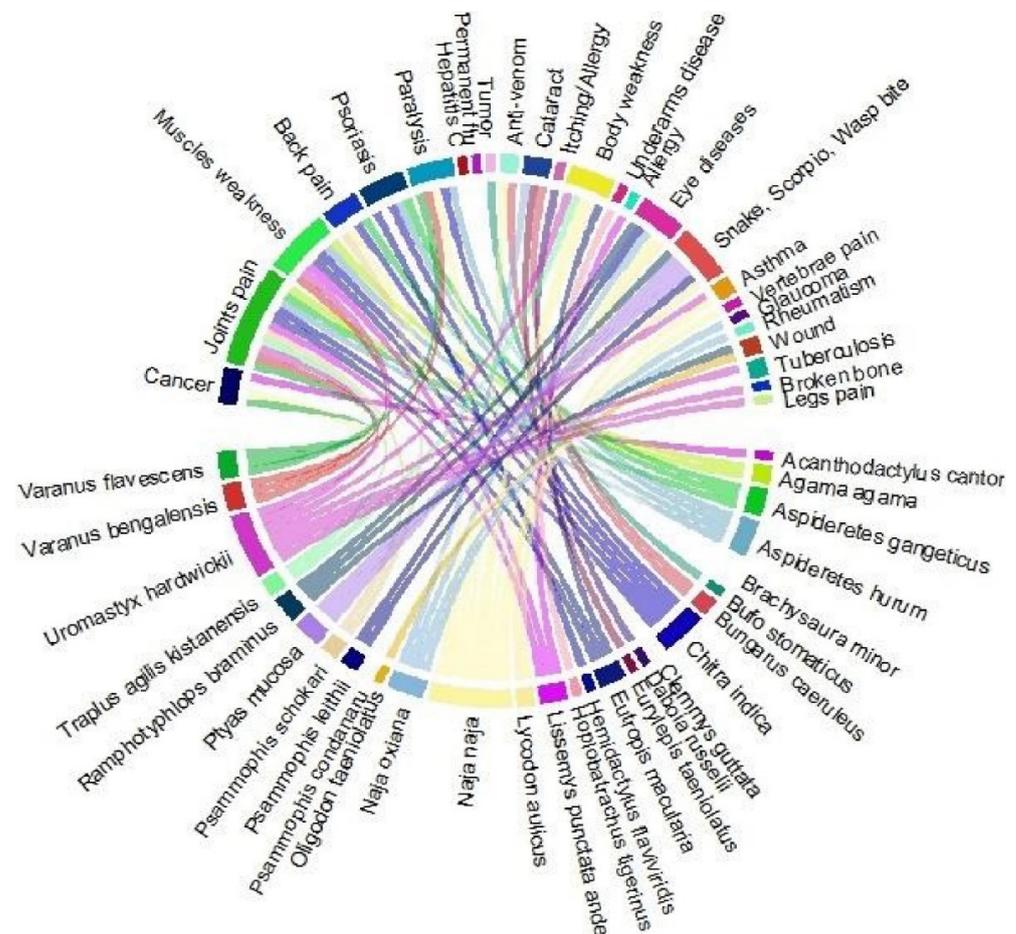

Figure 7. Body parts of animal species used in different recipes to treat various types of ailments.

Higher values of indices can be linked to the fact that certain amphibian and reptile species were the most used species by the highest number of informants (Table 2). High fidelity level values confirmed that these amphibian and reptile species were more frequently used for the treatment of various ailments [102,103]. These results are supported

by other scientists who reported amphibian and reptile species with high FL values that were employed to heal different human ailments [7,104], indicating that the native people of the study area held more information about the medicinal use of the documented species and less about conservation and sustainable information. Thus, the unfamiliarity of the people in the research region with respect to the ecology of amphibian and reptile species may cause their extinction.

*Varanus bengalensis*, a threatened species, was highly used in the study area for healing joint pain, body pain, paralysis, and arthritis (Figure 8). Hashmi et al. [105] reported that several tribes in Pakistan used the fat and oil of *V. bengalensis* as a salve for skin problems and to relieve rheumatic pain. The Bengal monitor lizard (*Varanus bengalensis*) is distributed throughout the Indus Valley, extending up to Las Bela in southern Baluchistan [106]. The lizard, when dipped in oil, is supposed to be used for the treatment of joint pain. Moreover, it is very popularly sold in Punjab, Pakistan (especially on footpaths, at bus stands, and at railway stations). The fat present in the body of a lizard is extracted and boiled down to the oil. The extracted oil is directly massaged on and around the treatment area. The active ingredients in oil are absorbed through the skin and into the body. There has been no medical research on lizard oil, but there have been clinical studies on a few of the popular herbs present in this oil mixture.

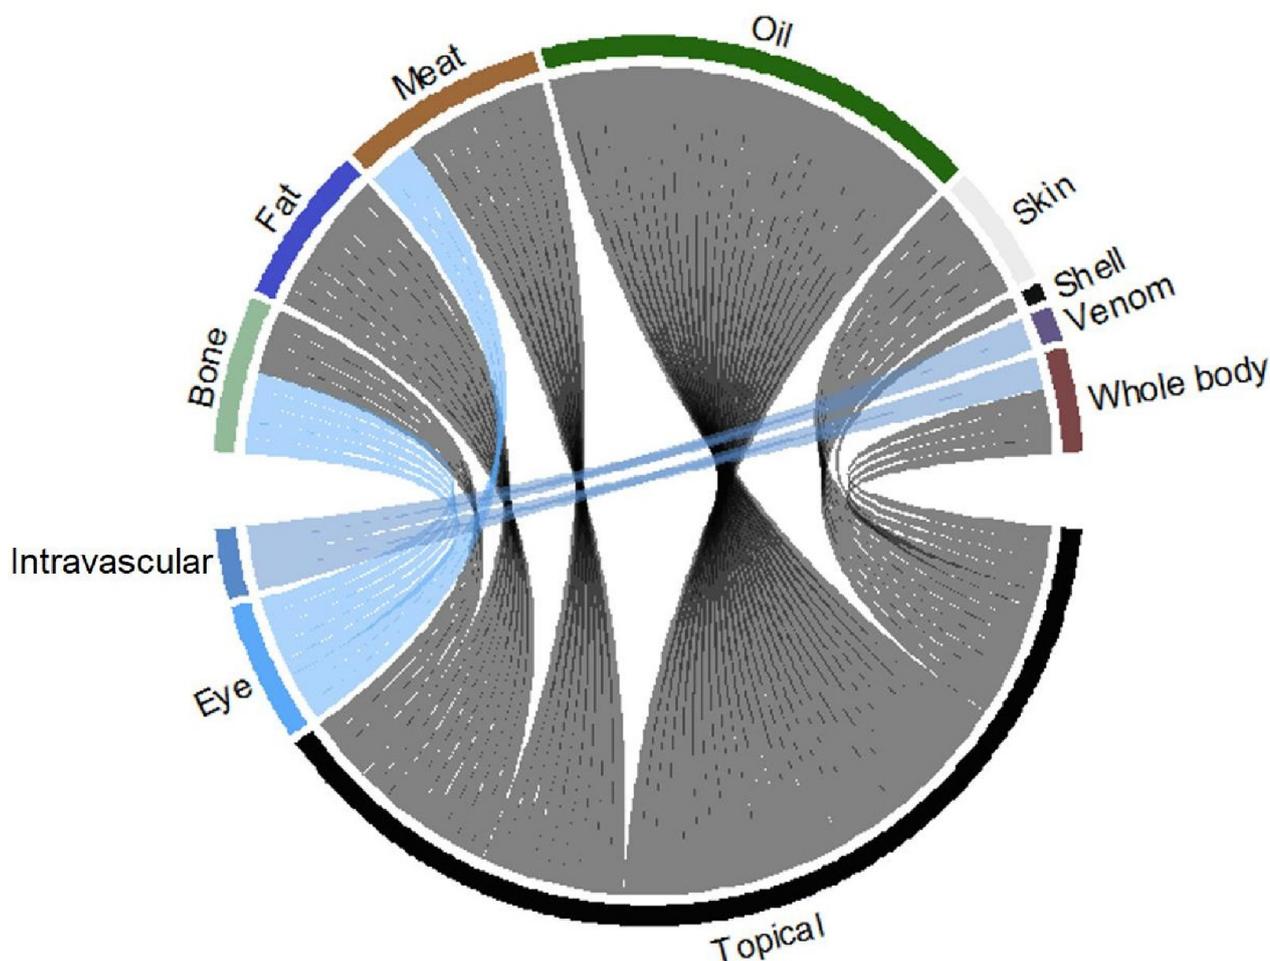

**Figure 8.** Animal species distribution according to the treatment of various ailments in Punjab, Pakistan.

#### 4.6. Body Part(s) Used

Oil was the most commonly used body part and was utilized in the synthesis of 26 recipes to treat various diseases, followed by the meat, bone, fat, skin, whole body, venom, and shell, which were used in 12, 9, 9, 7, 6, 2, and 1 recipes, respectively (Figure 9). People often exploited most animals by using derived products, such as oil (fat) [107,108],

eggs, blood, meat, shells, bones, and skin. Several other parts were also used as food, ornaments, drugs, and for magical and religious purposes [109–111].

**Figure 9.** Relationship between different methods of preparation and administration of herbal remedies.

The people of the Jhelum and Chenab rivers in Punjab use oil to treat paralysis, muscle stretching, body pain, muscle weakness, broken bone treatment, asthma, tuberculosis, and provide energy to remove body weakness. According to Hashmi et al. [105], oil extracted from the belly fat of reptile species was used to treat skin infection, joint pain, and as an aphrodisiac lubricant. The local people used fat to cure psoriasis, allergies, and as an energy source to remove body weakness. For example, fat and oil from *U. hardwickii* were considered to improve sexual potency and in the treatment of body pain, joint pain, and paralysis in the study area. This has been linked to the treatment of erectile dysfunction, rheumatism, backbone pain, body pain, arthritis, blindness, fever, colds, and memory enhancement [7].

Jhelum persons used meat to cure vertebral pain, backbone pain, wounds, snake bites, scorpion stings, wasp stings, cataracts, and eyesight problems (Figure 9). A few tribal people from Sindh, Pakistan, such as the Kohli, Bahri, Bheels, Jogis, and Thani, consume meat for medicinal purposes to relieve rheumatic pain [103]. Local people specifically hunted animals for meat. Meat of different animal species was utilized in different folk therapies, e.g., abscess, anemia, infertility, asthma, strength, bronchitis, memory, immune enhancer, epilepsy, menorrhagia, fever, flue, paralysis, skin diseases, wound healing, and sexual potency [20,79,81,83,85,112–115].

#### 4.7. Zoonotic Diseases

Wild animals and plants are very important for indigenous peoples and local communities for their cultural [116], medicinal [70,117–120], and esthetic values, and also serve as bioindicators [99]. Diseases can be transferred from animals to humans due to interactions with wildlife [121–123], and thus people who have close contact with animals can be at risk of zoonotic diseases [124,125]. Zoonotic pathogens can be transmitted from animals to humans, and transmitted from humans to other humans through sexual contact, vectors, aerosols, infected droplets, and oral transmission [126,127]. Many zoonotic diseases are transferred from amphibians to humans, including salmonellosis, sparganosis, and germs causing nausea, vomiting, and diarrhea [128,129]. Likewise, various zoonotic ailments are transmitted from reptiles to humans such as mycobacteriosis, pentastomiasis, and gastroenteritis [128,130,131]. This study found that direct usage of amphibians and reptiles has an influence not only on species diversity, but also on human health due to the documented spread of various zoonotic diseases.

#### 4.8. Conservational Aspects of the Encountered Species

The design and integration of biodiversity conservation plans requires understanding both the human–animal interactions and local use of natural resources [132]. In this context, documenting indigenous knowledge about animal-based remedies is extremely useful for the development of policies for sustainable use and restoration of natural resources [87]. Ethnobiological studies, in addition to providing information about traditional uses of fauna in any region, also cover the economic, traditional, and cultural value of animal species in human societies, and thus make a significant contribution to animal conservation efforts [43]. We found that 67.8% of the encountered species have so far not been evaluated with regard to their conservation status (NE), while 17.7% of species are currently listed as endangered (EN), 7.1% (*Bufo stomaticus* and *Sphaerotheca breviceps*) as least concern (LC), 3.6% (i.e., *Lissemys punctata andersoni*) as vulnerable (V), and 3.6% (i.e., *Varanus bengalensis*) are listed as near-threatened by the International Union of Conservation of Nature (Table 2 and Figure 10).

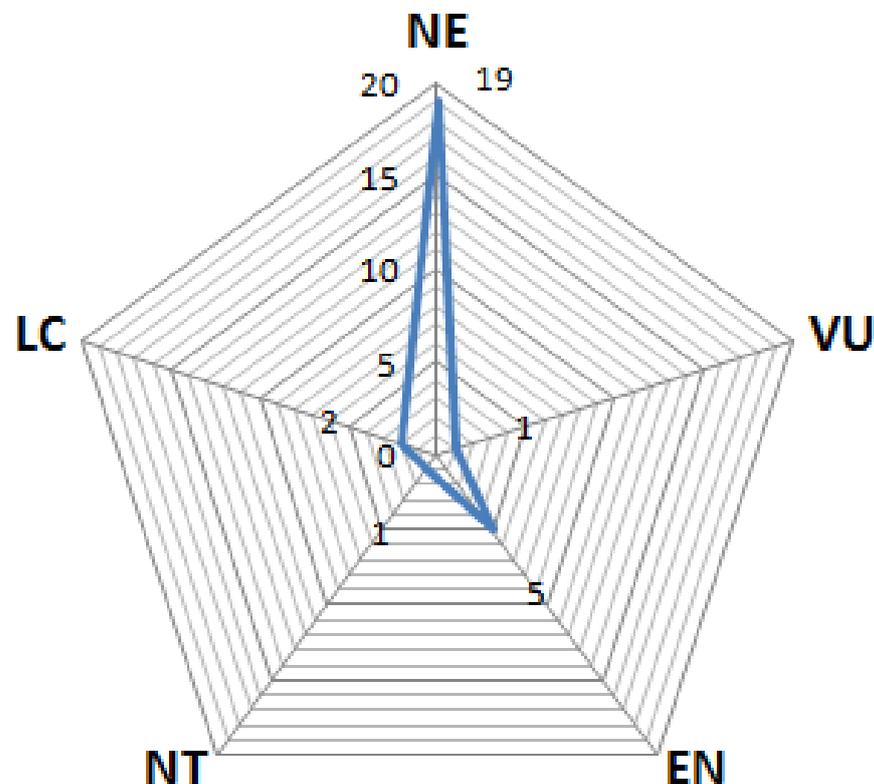

Figure 10. The conservation status of the species in the study area.

Surprisingly, most reptile and amphibian species (91%) in the region showed signs of danger, even though only 9% of them are currently categorized as endangered by the IUCN. The use of animal species for medicinal and other traditional uses is, however, not the sole threat to animal biodiversity in any location. Changes in temperature and other forms of interactions in an ecosystem all play a role in endangering animal populations and biodiversity [43,44]. Given the pressing need for answers to the present biodiversity loss catastrophe [45], particularly that of animal species, techniques that assess the problem in all of its complexity are required. For this reason, ethnozoology offers itself as a multidisciplinary approach that approaches the problem in a more comprehensive manner [40].

## 5. Conclusions

The current investigation discovered that indigenous peoples in the study area still use a wide variety of amphibian and reptile species in their healthcare systems. Traditional applications of different species were documented, to help conserve the traditional knowledge related to their use among the native people in the vicinity of the Jhelum and Chenab rivers in the Punjab province, Pakistan. A total of 26 reptiles and 2 amphibians were used in traditional medicine in the study area. Our results showed that the local people in the study area have access to broad traditional information due to of their connection with amphibian and reptile species. Some species, such as *Aspideretes gangeticus*, *A. hurum*, *Chitra indica*, *Varanus flavescens*, and *Geoclemys hamiltonii* were extensively used for the treatment of various ailments. Hunting, trade, and cultural use are the greatest threats to the diversity of amphibian and reptile species in the studied area, possibly leading to their final extinction. However, the present data will be useful for the assessment of the direct impact on the native fauna of the study area. With the involvement of local stakeholders, concerned authorities, academia, and conservation managers, immediate conservation measures should be taken for the protection and sustainable utilization of medicinal species.

**Supplementary Materials:** The following supporting information can be downloaded at <https://www.mdpi.com/article/10.3390/ani12162062/s1>, Table S1: Ethno-biological questionnaire form; Table S2: Inclusion and exclusion criteria for the survey.

**Author Contributions:** S.A. (Saba Adil) and M.A. prepared the first draft; S.A. (Saba Adil) and S.A. (Sana Ashraf) were involved in field surveys and data collection; A.M.A., R.W.B., T.H. and J.N. critically revised the manuscript; M.U., M.A. and A.M.A. were involved in data analysis, interpolation, and final write up. All authors have read and agreed to the published version of the manuscript.

**Funding:** This research received no external funding.

**Institutional Review Board Statement:** This study is based on a field survey rather than human or animal trials. So, ethical approval was not applicable. However, formal prior informed consent was taken from participants regarding data collection and publication. In addition, the ethical guidelines, and rules of the International Society of Ethnobiology (ISE) (<http://www.ethnobiology.net/> accessed on 12 July 2018) were strictly followed.

**Informed Consent Statement:** Not applicable.

**Data Availability Statement:** All the data are presented in the tables and figures in the article or as a Supplementary Material, and further inquiries can be directed to the corresponding authors.

**Acknowledgments:** The authors are grateful to the residents of the research area for sharing useful information for the study. Instead of human or animal tracks, the current study relied only on a field survey. As a result, no ethical approval or agreement to participate was required. Informants, on the other hand, gave their official agreement to data gathering and publication. This research was carried out entirely on a self-financing basis, with no outside funding.

**Conflicts of Interest:** The authors declare no conflict of interest.
